

Process Scheduling

Process scheduling is the activity of the operating system that decides which process runs on the CPU at any given time.

Common algorithms include First-Come First-Served, Shortest Job First, Round Robin, and Priority Scheduling.

Deadlocks

A deadlock occurs when a set of processes are each waiting for a resource held by another process in the set, so none of them can proceed. The four necessary conditions are mutual exclusion, hold and wait, no preemption, and circular wait.
